# 1 Analysis of finite difference equations

Model:

$$u'(t) = -au(t), \quad u(0) = I$$
 (1)

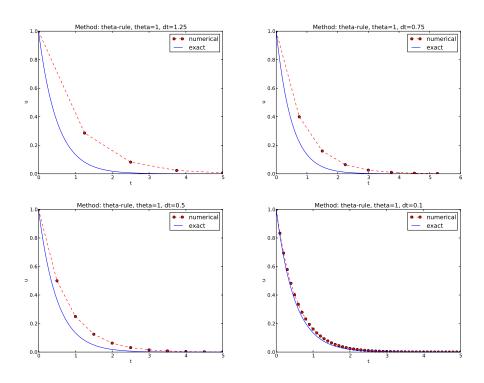

Method:

$$u^{n+1} = \frac{1 - (1 - \theta)a\Delta t}{1 + \theta a\Delta t} u^n \tag{2}$$

**Problem setting.** How good is this method? Is it safe to use it?

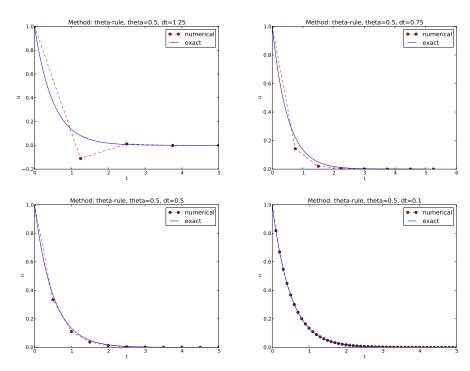

#### 1.1 Encouraging numerical solutions

 $I = 1, a = 2, \theta = 1, 0.5, 0, \Delta t = 1.25, 0.75, 0.5, 0.1.$ 

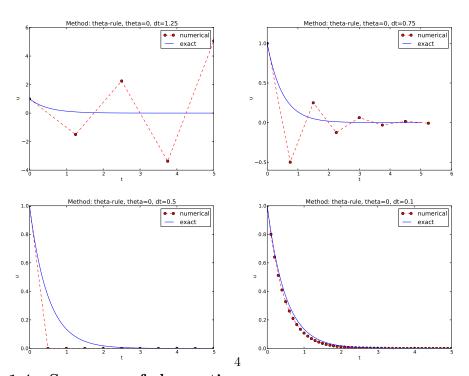

## 1.2 Discouraging numerical solutions; Crank-Nicolson

# 1.3 Discouraging numerical solutions; Forward Euler

## 1.4 Summary of observations

The characteristics of the displayed curves can be summarized as follows:

- $\bullet$  The Backward Euler scheme always gives a monotone solution, lying above the exact curve.
- The Crank-Nicolson scheme gives the most accurate results, but for  $\Delta t = 1.25$  the solution oscillates.
- The Forward Euler scheme gives a growing, oscillating solution for  $\Delta t = 1.25$ ; a decaying, oscillating solution for  $\Delta t = 0.75$ ; a strange solution  $u^n = 0$  for  $n \ge 1$  when  $\Delta t = 0.5$ ; and a solution seemingly as accurate as the one by the Backward Euler scheme for  $\Delta t = 0.1$ , but the curve lies below the exact solution.

#### 1.5 Problem setting

Goal. We ask the question

• Under what circumstances, i.e., values of the input data I, a, and  $\Delta t$  will the Forward Euler and Crank-Nicolson schemes result in undesired oscillatory solutions?

Techniques of investigation:

- Numerical experiments
- Mathematical analysis

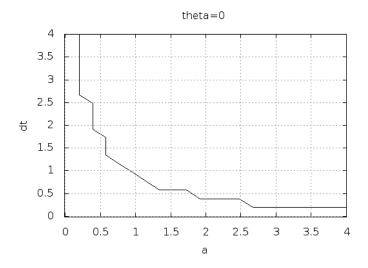

Another question to be raised is

• How does  $\Delta t$  impact the error in the numerical solution?

#### 1.6 Experimental investigation of oscillatory solutions

The solution is oscillatory if

$$u^n > u^{n-1}$$

Seems that  $a\Delta t < 1$  for FE and 2 for CN.

#### 1.7 Exact numerical solution

Starting with  $u^0=I,$  the simple recursion (2) can be applied repeatedly n times, with the result that

$$u^{n} = IA^{n}, \quad A = \frac{1 - (1 - \theta)a\Delta t}{1 + \theta a\Delta t}$$
(3)

Such an exact discrete solution is unusual, but very handy for analysis.

#### 1.8 Stability

Since  $u^n \sim A^n$ ,

- A < 0 gives a factor  $(-1)^n$  and oscillatory solutions
- |A| > 1 gives growing solutions
- Recall: the exact solution is monotone and decaying
- ullet If these qualitative properties are not met, we say that the numerical solution is unstable

#### 1.9 Computation of stability in this problem

A < 0 if

$$\frac{1 - (1 - \theta)a\Delta t}{1 + \theta a\Delta t} < 0$$

To avoid oscillatory solutions we must have A > 0 and

$$\Delta t < \frac{1}{(1-\theta)a} \tag{4}$$

- Always fulfilled for Backward Euler
- $\Delta t \leq 1/a$  for Forward Euler
- $\Delta t \leq 2/a$  for Crank-Nicolson

# 1.10 Computation of stability in this problem

 $|A| \le 1$  means  $-1 \le A \le 1$ 

$$-1 \le \frac{1 - (1 - \theta)a\Delta t}{1 + \theta a\Delta t} \le 1 \tag{5}$$

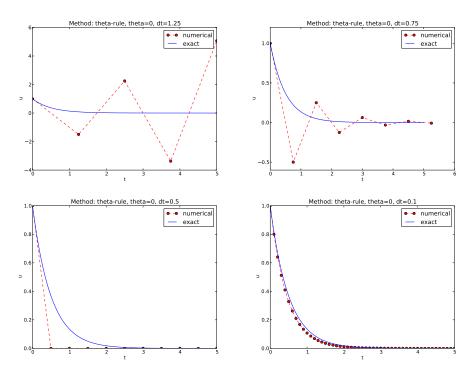

-1 is the critical limit:

$$\Delta t \le \frac{2}{(1-2\theta)a}, \quad \theta < \frac{1}{2}$$

$$\Delta t \ge \frac{2}{(1-2\theta)a}, \quad \theta > \frac{1}{2}$$

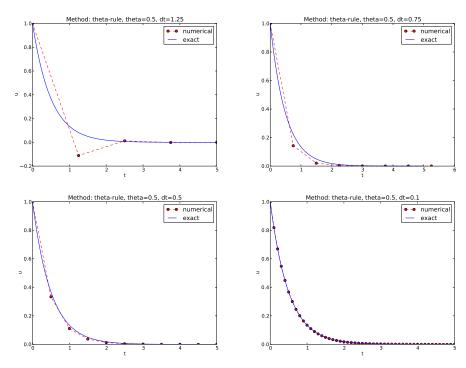

- Always fulfilled for Backward Euler and Crank-Nicolson
- $\Delta t \leq 2/a$  for Forward Euler

# 1.11 Explanation of problems with Forward Euler

- $a\Delta t = 2 \cdot 1.25 = 2.5$  and A = -1.5: oscillations and growth
- $a\Delta t = 2 \cdot 0.75 = 1.5$  and A = -0.5: oscillations and decay
- $\Delta t = 0.5$  and A = 0:  $u^n = 0$  for n > 0
- ullet Smaller Deltat: qualitatively correct solution

## 1.12 Explanation of problems with Crank-Nicolson

- $\Delta t = 1.25$  and A = -0.25: oscillatory solution
- Never any growing solution

#### 1.13 Summary of stability

- 1. Forward Euler is  $conditionally\ stable$ 
  - $\Delta t < 2/a$  for avoiding growth
  - $\Delta t \leq 1/a$  for avoiding oscillations
- 2. The Crank-Nicolson is unconditionally stable wrt growth and conditionally stable wrt oscillations
  - $\Delta t < 2/a$  for avoiding oscillations
- 3. Backward Euler is unconditionally stable

#### 1.14 Comparing amplification factors

 $u^{n+1}$  is an amplification A of  $u^n$ :

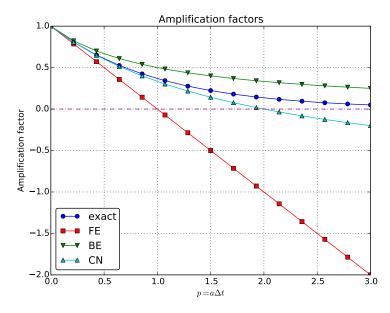

$$u^{n+1} = Au^n$$
,  $A = \frac{1 - (1 - \theta)a\Delta t}{1 + \theta a\Delta t}$ 

The exact solution is also an amplification:

$$u(t_{n+1}) = A_{\mathbf{e}}u(t_n), \quad A_{\mathbf{e}} = e^{-a\Delta t}$$

A possible measure of accuracy:  $A_{\rm e}-A$ 

#### 1.15 Plot of amplification factors

# 1.16 $p = a\Delta t$ is the important parameter for numerical performance

- $p = a\Delta t$  is a dimensionless parameter
- $\bullet$  all expressions for stability and accuracy involve p
- Note that  $\Delta t$  alone is not so important, it is the combination with a through  $p = a\Delta t$  that matters

Another "proof" why  $p = a\Delta t$  is key. If we scale the model by  $\bar{t} = at$ ,  $\bar{u} = u/I$ , we get  $d\bar{u}/d\bar{t} = -\bar{u}$ ,  $\bar{u}(0) = 1$  (no physical parameters!). The analysis show that  $\Delta \bar{t}$  is key, corresponding to  $a\Delta t$  in the unscaled model.

#### 1.17 Series expansion of amplification factors

To investigate  $A_{\rm e}-A$  mathematically, we can Taylor expand the expression, using  $p=a\Delta t$  as variable.

```
>>> from sympy import *
>>> # Create p as a mathematical symbol with name 'p'
>>> p = Symbol('p')
>>> # Create a mathematical expression with p
>>> A_e = exp(-p)
>>>
>>> # Find the first 6 terms of the Taylor series of A_e
>>> A_e.series(p, 0, 6)
1 + (1/2)*p**2 - p - 1/6*p**3 - 1/120*p**5 + (1/24)*p**4 + 0(p**6)
>>> theta = Symbol('theta')
>>> A = (1-(1-theta)*p)/(1+theta*p)
>>> FE = A_e.series(p, 0, 4) - A.subs(theta, 0).series(p, 0, 4)
>>> BE = A_e.series(p, 0, 4) - A.subs(theta, 1).series(p, 0, 4)
>>> half = Rational(1,2) # exact fraction 1/2
>>> CN = A_e.series(p, 0, 4) - A.subs(theta, half).series(p, 0, 4)
(1/2)*p**2 - 1/6*p**3 + 0(p**4)
>>> BE
-1/2*p**2 + (5/6)*p**3 + 0(p**4)
>>> CN
(1/12)*p**3 + 0(p**4)
```

#### 1.18 Error in amplification factors

Focus: the error measure  $A - A_e$  as function of  $\Delta t$  (recall that  $p = a\Delta t$ ):

$$A - A_{\rm e} = \begin{cases} \mathcal{O}(\Delta t^2), & \text{Forward and Backward Euler,} \\ \mathcal{O}(\Delta t^3), & \text{Crank-Nicolson} \end{cases}$$
 (6)

# 1.19 The fraction of numerical and exact amplification factors

Focus: the error measure  $1 - A/A_e$  as function of  $p = a\Delta t$ :

```
>>> FE = 1 - (A.subs(theta, 0)/A_e).series(p, 0, 4)
>>> BE = 1 - (A.subs(theta, 1)/A_e).series(p, 0, 4)
>>> CN = 1 - (A.subs(theta, half)/A_e).series(p, 0, 4)
>>> FE
(1/2)*p**2 + (1/3)*p**3 + 0(p**4)
```

```
>>> BE
-1/2*p**2 + (1/3)*p**3 + 0(p**4)
>>> CN
(1/12)*p**3 + 0(p**4)
```

Same leading-order terms as for the error measure  $A - A_e$ .

#### 1.20 The true/global error at a point

- ullet The error in A reflects the  $local\ error$  when going from one time step to the next
- What is the global (true) error at  $t_n$ ?  $e^n = u_e(t_n) u^n = Ie^{-at_n} IA^n$
- Taylor series expansions of  $e^n$  simplify the expression

#### 1.21 Computing the global error at a point

```
>>> n = Symbol('n')
>>> u_e = exp(-p*n)  # I=1
>>> u_n = A**n  # I=1
>>> FE = u_e.series(p, 0, 4) - u_n.subs(theta, 0).series(p, 0, 4)
>>> BE = u_e.series(p, 0, 4) - u_n.subs(theta, 1).series(p, 0, 4)
>>> CN = u_e.series(p, 0, 4) - u_n.subs(theta, half).series(p, 0, 4)
>>> FE
(1/2)*n*p**2 - 1/2*n**2*p**3 + (1/3)*n*p**3 + 0(p**4)
>>> BE
(1/2)*n**2*p**3 - 1/2*n*p**2 + (1/3)*n*p**3 + 0(p**4)
>>> CN
(1/12)*n*p**3 + 0(p**4)
```

Substitute n by  $t/\Delta t$ :

- $\bullet$  Crank-Nicolson: leading order term  $\frac{1}{12}ta^3\Delta t^2$

#### 1.22 Convergence

The numerical scheme is convergent if the global error  $e^n \to 0$  as  $\Delta t \to 0$ . If the error has a leading order term  $\Delta t^r$ , the convergence rate is of order r.

#### 1.23 Integrated errors

Focus: norm of the numerical error

$$||e^n||_{\ell^2} = \sqrt{\Delta t \sum_{n=0}^{N_t} (u_e(t_n) - u^n)^2}$$

Forward and Backward Euler:

$$||e^n||_{\ell^2} = \frac{1}{4}\sqrt{\frac{T^3}{3}}a^2\Delta t$$

Crank-Nicolson:

$$||e^n||_{\ell^2} = \frac{1}{12} \sqrt{\frac{T^3}{3}} a^3 \Delta t^2$$

**Summary of errors.** Analysis of both the pointwise and the time-integrated true errors:

- 1st order for Forward and Backward Euler
- 2nd order for Crank-Nicolson

#### 1.24 Truncation error

- How good is the discrete equation?
- $\bullet$  Possible answer: see how well  $u_{\rm e}$  fits the discrete equation

$$[D_t u = -au]^n$$

i.e.,

$$\frac{u^{n+1} - u^n}{\Delta t} = -au^n$$

Insert  $u_{\rm e}$  (which does not in general fulfill this equation):

$$\frac{u_{e}(t_{n+1}) - u_{e}(t_{n})}{\Delta t} + au_{e}(t_{n}) = R^{n} \neq 0$$
 (7)

#### 1.25 Computation of the truncation error

- The residual  $R^n$  is the truncation error.
- How does  $R^n$  vary with  $\Delta t$ ?

Tool: Taylor expand  $u_e$  around the point where the ODE is sampled (here  $t_n$ )

$$u_{e}(t_{n+1}) = u_{e}(t_{n}) + u'_{e}(t_{n})\Delta t + \frac{1}{2}u''_{e}(t_{n})\Delta t^{2} + \cdots$$

Inserting this Taylor series in (7) gives

$$R^{n} = u'_{e}(t_{n}) + \frac{1}{2}u''_{e}(t_{n})\Delta t + \ldots + au_{e}(t_{n})$$

Now,  $u_e$  solves the ODE  $u'_e = -au_e$ , and then

$$R^n \approx \frac{1}{2} u_{\rm e}''(t_n) \Delta t$$

This is a mathematical expression for the truncation error.

#### 1.26 The truncation error for other schemes

Backward Euler:

$$R^n \approx -\frac{1}{2}u''_{\rm e}(t_n)\Delta t$$

Crank-Nicolson:

$$R^{n+\frac{1}{2}} \approx \frac{1}{24} u_{\rm e}^{""}(t_{n+\frac{1}{2}}) \Delta t^2$$

#### 1.27 Consistency, stability, and convergence

- Truncation error measures the residual in the difference equations. The scheme is *consistent* if the truncation error goes to 0 as  $\Delta t \to 0$ . Importance: the difference equations approaches the differential equation as  $\Delta t \to 0$ .
- Stability means that the numerical solution exhibits the same qualitative properties as the exact solution. Here: monotone, decaying function.
- Convergence implies that the true (global) error  $e^n = u_e(t_n) u^n \to 0$  as  $\Delta t \to 0$ . This is really what we want!

The Lax equivalence theorem for *linear* differential equations: consistency + stability is equivalent with convergence.

(Consistency and stability is in most problems much easier to establish than convergence.)
